## Introduction

## Homotopy theory

#### CW-complexes

**Definition o.o.1.** A map  $f: X \to Y$  is called a *weak homotopy equivalence* if it induces isomorphisms

$$\pi_n(X, x_0) \to \pi_n(Y, f(x_0))$$

for all  $n \ge 0$  and all choices of basepoints  $x_0$  in X.

**Theorem o.o.2** (Whitehead's Theorem). *A weak homotopy equivalence between CW-complexes is a homotopy equivalence.* 

**Proposition o.o.3** (Geometric interpretation of *n*-connectedness). *If* (X, A) *is an n-connected CW-pair, then there exists a CW-pair*  $(Z, A) \sim_{\operatorname{rel} A} (X, A)$  *such that all cells of*  $Z \setminus A$  *have dimension greater than n.* 

### Homology

**Definition o.o.4** (Acyclic). A space X is called *acyclic* if  $\widetilde{H}_i(X) = 0$  for all i, i.e. if its reduced homology vanishes.

**Example o.o.5.** Removing a point from a homology sphere yields an acyclic space. This example for the Poincare homology sphere is described in TODO Insert proof.

## **Knot Theory**

#### **Definitions**

**Definition o.o.6.** If *K* is an oriented knot, then

- the *reverse*  $\overline{K}$  is K with the opposite orientation
- the *obverse rK* is the reflection of *K* in a plane
- the *inverse*  $r\overline{K}$  is the concordance inverse of K.

**Proposition o.o.7.** For  $K \subset \mathbb{S}^3$  we have that  $K \# r \overline{K}$  is slice, even ribbon.

Alexander polynomial

**Definition o.o.8.** *L* oriented link with Seifert matrix *A*, then the first homology of the infinite cyclic covering of the link complement,  $H_1(X_\infty; \mathbb{Z})$ , has square presentation matrix  $tA - A^T$ .

The Alexander polynomial of L is given by

$$\Delta_L(t) \doteq \det(tA - A^T)$$

where  $\doteq$  means "up to a multiplication with a unit  $\{\pm t^{\pm n}\}$  of the Laurent ring  $\mathbb{Z}[t, t^{-1}]$ ".

*Remark* o.o.9.  $\mathbb{Z}[t^{\pm 1}]$  is **not** a PID.

**Invariants** 

**Definition o.o.10.** The tunnel number t(K) of a knot  $K \subset \mathbb{S}^3$  is the minimal number of arcs that must be added to the knot (forming a graph with three edges at a vertex) so that its complement in  $\mathbb{S}^3$  is a handlebody. The same definition is valid for links.

The boundary will be a minimal Heegaard splitting of the knot complement (The knot complement is a manifold with boundary, so what is the definition of a Heegard splitting in that case?).

*Remark* 0.0.11. Every link has a tunnel number, this can be seen by adding a "vertical" tunnel at every crossing in a link diagram. This

shows that the tunnel number of a knot is always less than or equal to the crossing number,  $t(K) \le c(K)$ .

**Example o.o.12.** • *The unknot is the only knot with tunnel number o. (Why?)* 

- The trefoil knot has tunnel number 1.
- The figure eight knot has tunnel number 1.

### Open questions

**Open question 1.** *Is the crossing number of a satellite knot bigger than that of its companion?*
